# 3.2 - Forest growth/dynamics (practice)

Miquel De Cáceres, Victor Granda, Aitor Ameztegui

**Ecosystem Modelling Facility** 

2022-06-15

## **Outline**

- 1. Forest growth inputs
- 2. Running forest growth
- 3. Evaluation of growth predictions
  - 4. Forest dynamics

## Creating the forest growth input object

We assume we have an appropriate forest object:

data(exampleforestMED)

## Creating the forest growth input object

We assume we have an appropriate forest object:

```
data(exampleforestMED)
```

a species parameter data frame:

```
data(SpParamsMED)
```

## Creating the forest growth input object

We assume we have an appropriate forest object:

```
data(exampleforestMED)

a species parameter data frame:

data(SpParamsMED)

a soil input object:

examplesoil <- soil(defaultSoilParams(4))</pre>
```

## Creating the forest growth input object

We assume we have an appropriate forest object:

```
data(exampleforestMED)
a species parameter data frame:
    data(SpParamsMED)
a soil input object:
    examplesoil <- soil(defaultSoilParams(4))
and simulation control list:
    control <- defaultControl("Granier")</pre>
```

### Creating the forest growth input object

We assume we have an appropriate forest object:

```
data(exampleforestMED)
a species parameter data frame:
   data(SpParamsMED)
a soil input object:
   examplesoil <- soil(defaultSoilParams(4))
and simulation control list:
   control <- defaultControl("Granier")</pre>
```

With these four elements we can build our input object for function growth():

```
x <- forest2growthInput(exampleforestMED, examplesoil, SpParamsMED, control)
```

### Structure of the growth input object (1)

The growth input object is a list with several elements:

```
names(x)
   [1] "control"
                                                     "canopy"
                              "soil"
                                                                           "cohorts"
   [5] "above"
                                                     "belowLayers"
                                                                           "paramsPhenology"
                              "below"
   [9] "paramsAnatomy"
                                                     "paramsTranspiration" "paramsWaterStorage"
                              "paramsInterception"
                                                                           "internalWater"
## [13] "paramsGrowth"
                              "paramsAllometries"
                                                     "internalPhenology"
  [17] "internalCarbon"
                              "internalAllocation"
                                                     "internalMortality"
```

### Structure of the growth input object (1)

The growth input object is a list with several elements:

```
names(x)
   [1] "control"
                                                    "canopy"
                              "soil"
                                                                           "cohorts"
## [5] "above"
                                                    "belowLayers"
                              "below"
                                                                           "paramsPhenology"
                                                    "paramsTranspiration" "paramsWaterStorage"
## [9] "paramsAnatomy"
                              "paramsInterception"
## [13] "paramsGrowth"
                              "paramsAllometries"
                                                     "internalPhenology"
                                                                           "internalWater"
## [17] "internalCarbon"
                              "internalAllocation"
                                                    "internalMortality"
```

Element above contains the above-ground structure data that we already know, but with an additional column SA that describes the estimated initial amount of *sapwood area*:

```
## SP N DBH Cover H CR SA LAI_live LAI_expanded LAI_dead
## T1_148 148 168.0000 37.55 NA 800 0.6605196 437.032040 0.96734365 0.96734365 0
## T2_168 168 384.0000 14.60 NA 660 0.6055642 57.407064 0.86167321 0.86167321 0

## S1_165 0.7223526 0.00925123 0.2857655 3.445161
```

#### Forest growth run

The call to function growth() needs the growth input object, the weather data frame, latitude and elevation:

```
G \leftarrow growth(x, examplemeteo, latitude = 41.82592, elevation = 100)
## Package 'meteoland' [ver. 1.0.3]
## Initial plant cohort biomass (g/m2): 7109.27
## Initial soil water content (mm): 291.257
## Initial snowpack content (mm): 0
## Performing daily simulations
##
   Year 2001:.....
##
## Final plant biomass (g/m2): 7411.44
## Change in plant biomass (g/m2): 302.171
## Plant biomass balance result (g/m2): 302.171
## Plant biomass balance components:
    Structural balance (g/m2) 204 Labile balance (g/m2) 126
    Plant individual balance (g/m2) 331 Mortality loss (g/m2) 28
## Final soil water content (mm): 268.717
## Final snowpack content (mm): 0
## Change in soil water content (mm): -22.5396
## Soil water balance result (mm): -22.5396
## Change in snowpack water content (mm): 0
## Snowpack water balance result (mm): 0
## Water balance components:
    Precipitation (mm) 513
##
    Rain (mm) 462 Snow (mm) 51
##
    Interception (mm) 95 Net rainfall (mm) 367
```

## Growth output object

Function growth() returns an object of class with the same name, actually a list:

```
class(G)
## [1] "growth" "list"
```

#### ... whose elements are:

Elements	Information
<pre>latitude, topography, weather, growthInput</pre>	Copies of the information used in the call to growth()
growthOutput	State variables at the end of the simulation (can be used as input to a subsequent one)
WaterBalance, Soil, Stand, Plants	[same as spwb]
LabileCarbonBalance	Components of the labile carbon balance
PlantBiomassBalance	Components of indvidual- and cohort-level biomass balance
PlantStructure	Structural variables (DBH, height, sapwood area)
GrowthMortality	Growth and mortality rates
subdaily	Sub-daily outputs (not relevant here)

#### Plots and summaries

Users can inspect the output of growth() simulations using functions summary() and plot() on the simulation output.

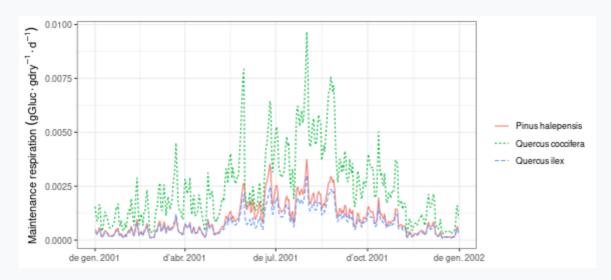

#### Plots and summaries

Users can inspect the output of growth() simulations using functions summary() and plot() on the simulation output.

Several new plots are available in addition to those available for spwb() simulations (see ? plot.growth). For example:

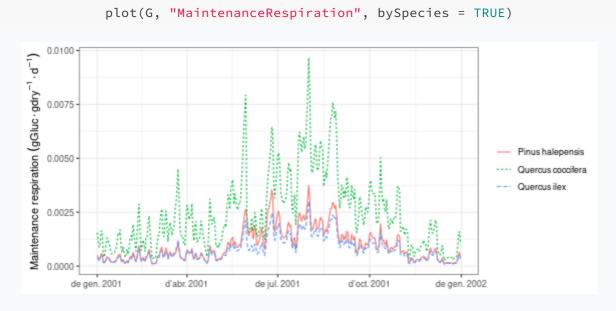

#### Plots and summaries

Users can inspect the output of growth() simulations using functions summary() and plot() on the simulation output.

Several new plots are available in addition to those available for spwb() simulations (see ? plot.growth). For example:

... but instead of typing all plots, we can call the interactive plot function shinyplot().

#### Observed data frame

Evaluation of growth simulations will normally imply the comparison of predicted vs observed **basal** area increment (BAI) or diameter increment (DI) at a given temporal resolution.

#### Observed data frame

Evaluation of growth simulations will normally imply the comparison of predicted vs observed **basal** area increment (BAI) or diameter increment (DI) at a given temporal resolution.

Here, we illustrate the evaluation functions included in the package using a fake data set at *daily* resolution, consisting on the predicted values and some added error.

```

#### Observed data frame

Evaluation of growth simulations will normally imply the comparison of predicted vs observed **basal area increment** (BAI) or **diameter increment** (DI) at a given temporal resolution.

Here, we illustrate the evaluation functions included in the package using a fake data set at *daily* resolution, consisting on the predicted values and some added error.

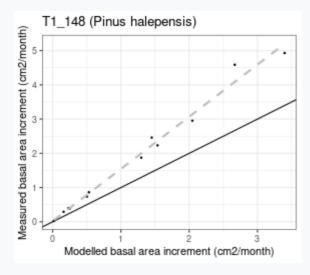

```
data(exampleobs)
head(exampleobs)

```

To specify observed growth data at *monthly* or *annual scale*, you should specify the first day of each month/year (e.g. 2001-01-01, 2002-01-01, etc for years) as row names in your observed data frame.

#### **Evaluation plot**

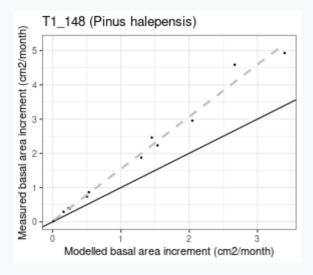

Assuming we want to evaluate the predictive capacity of the model in terms of monthly basal area increment for the *pine cohort* (i.e. T1\_148), we can plot the relationship between observed and predicted values using evaluation\_plot():

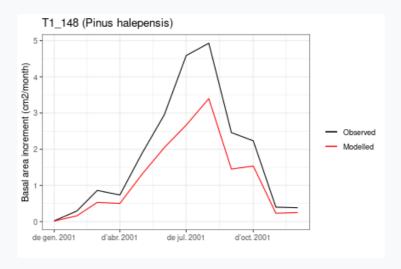

#### **Evaluation plot**

Assuming we want to evaluate the predictive capacity of the model in terms of monthly basal area increment for the *pine cohort* (i.e. T1\_148), we can plot the relationship between observed and predicted values using evaluation\_plot():

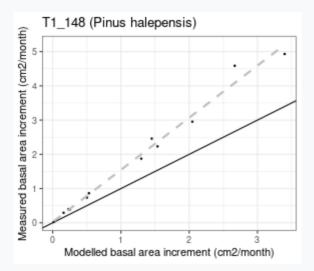

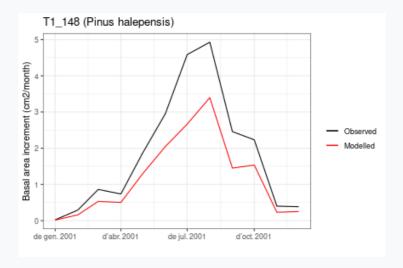

#### **Evaluation plot**

Assuming we want to evaluate the predictive capacity of the model in terms of monthly basal area increment for the *pine cohort* (i.e. T1\_148), we can plot the relationship between observed and predicted values using evaluation\_plot():

Using temporalResolution = "month" we indicate that simulated and observed data should be temporally aggregated to conduct the comparison.

#### **Evaluation metrics**

The following code would help us quantifying the *strength* of the relationship:

## Weather preparation

In this vignette we will fake a three-year weather input by repeating the example weather data frame three times:

```
meteo = rbind(examplemeteo, examplemeteo)
```

## Weather preparation

In this vignette we will fake a three-year weather input by repeating the example weather data frame three times:

```
meteo = rbind(examplemeteo, examplemeteo, examplemeteo)
```

we need to update the dates in row names so that they span three consecutive years:

```
row.names(meteo) = seq(as.Date("2001-01-01"),
as.Date("2003-12-31"), by="day")
```

#### **Simulation**

**Remember**: fordyn() operates on forest objects directly, instead of using an intermediary object (such as spwbInput and growthInput).

#### **Simulation**

**Remember**: fordyn() operates on forest objects directly, instead of using an intermediary object (such as spwbInput and growthInput).

**Important**: fordyn() calls function growth() internally for each simulated year.

#### Simulation

**Remember**: fordyn() operates on forest objects directly, instead of using an intermediary object (such as spwbInput and growthInput).

**Important**: fordyn() calls function growth() internally for each simulated year.

The verbose option of the control parameters only affects function fordyn(), i.e. all console output from growth() is hidden.

## Forest dynamics output

As with other models, the output of fordyn() is a list, which has the following elements:

Elements	Information
StandSummary, SpeciesSummary, CohortSummary	Annual summary statistics at different levels
TreeTable, ShrubTable	Structural variables of <b>living</b> cohorts at each annual time step.
DeadTreeTable, DeadShrubTable	Structural variables of <b>dead</b> cohorts at each annual time step
CutTreeTable, CutShrubTable	Structural variables of <b>cut</b> cohorts at each annual time step
ForestStructures	Vector of forest objects at each time step.
GrowthResults	Result of internally calling growth() at each time step.
ManagementArgs	Management arguments for a subsequent call to fordyn().
NextInputObject, NextForestObject	Objects growthInput and forest to be used in a subsequent call to fordyn().

#### Forest dynamics output

For example, we can compare the initial forest object with the final one:

```
exampleforestMED
                                                    fd$NextForestObject
                                                    ## $ID

## Summaries and plots

The provides a plot function for objects of class fordyn. For example, we can show the year-to-year variation in stand-level basal area using:

plot(fd, type = "StandBasalArea")

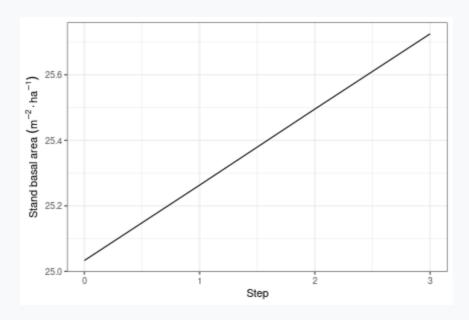

#### Summaries and plots

The provides a plot function for objects of class fordyn. For example, we can show the year-to-year variation in stand-level basal area using:

plot(fd, type = "StandBasalArea")

These plots are based on the *annual summaries* included in the output.

### Summaries and plots

**Remember**: Function fordyn() makes internal calls to function growth() and stores the result in a vector called GrowthResults.

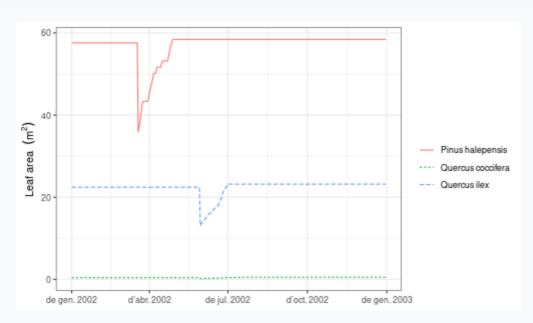

#### Summaries and plots

**Remember**: Function fordyn() makes internal calls to function growth() and stores the result in a vector called GrowthResults.

Accessing elements of GrowthResults, we can summarize or plot simulation results for a particular year:

### Summaries and plots

It is also possible to plot the whole series of results by passing a fordyn object to the plot() function:

#### Summaries and plots

It is also possible to plot the whole series of results by passing a fordyn object to the plot() function:

In this case, the plot() function assembles all the information from GrowthResults (accounting for cohort additions/deletions) and draws the plot.

#### Summaries and plots

It is also possible to plot the whole series of results by passing a fordyn object to the plot() function:

In this case, the plot() function assembles all the information from GrowthResults (accounting for cohort additions/deletions) and draws the plot.

Finally, we can create interactive plots using function shinyplot(), in the same way as with other simulations.

### Forest dynamics including management

fordyn() allows the user to supply an *arbitrary* function implementing a desired management strategy for the stand whose dynamics are to be simulated.

#### Forest dynamics including management

fordyn() allows the user to supply an *arbitrary* function implementing a desired management strategy for the stand whose dynamics are to be simulated.

The package includes an in-built default function called defaultManagementFunction() along with a flexible parameterization, a list with defaults provided by function defaultManagementArguments().

#### Forest dynamics including management

fordyn() allows the user to supply an *arbitrary* function implementing a desired management strategy for the stand whose dynamics are to be simulated.

The package includes an in-built default function called defaultManagementFunction() along with a flexible parameterization, a list with defaults provided by function defaultManagementArguments().

To run simulations with management we need to define (and modify) management arguments (see ? defaultManagementArguments)...

```
# Default arguments
args <- defaultManagementArguments()
# Here one can modify defaults before calling fordyn()
#</pre>
```

# Here one can modify defaults before calling fordyn()
#</pre>
```

... and call fordyn() specifying the management function and its arguments:

When management is included, two additional tables are produced, e.g.:

```
fd$CutTreeTable
fd$CutShrubTable
```

### Forest dynamics including management

Function defaultManagementArguments() returns a list with default values for *management* parameters:

Element	Description
type	Management model, either 'regular' or 'irregular'
thinning	Kind of thinning to be applied in irregular models or in regular models before the final cuts. Options are "below", "above", "systematic", "below-systematic", "above-systematic" or a string with the proportion of cuts to be applied to different diameter sizes
thinningMetric	The stand-level metric used to decide whether thinning is applied, either "BA" (basal area), "N" (density) or "HB" (Hart-Becking index)
thinningThreshold	The threshold value of the stand-level metric causing the thinning decision
thinningPerc	Percentage of stand's basal area to be removed in thinning operations
minThinningInterval	Minimum number of years between thinning operations
finalMeanDBH	Mean DBH threshold to start final cuts
finalPerc	String with percentages of basal area to be removed in final cuts, separated by '-' (e.g. "40-60-100")
finalYearsBetweenCuts	Number of years separating final cuts

### Forest dynamics including management

The same list includes *state variables* for management (these are modified during the simulation):

Element	Description
yearsSinceThinning	State variable to count the years since the last thinning ocurred
finalPreviousStage	Integer state variable to store the stage of final cuts ('0' before starting final cuts)
finalYearsToCut	State variable to count the years to be passed before new final cut is applied.

#### Forest dynamics including management

The same list includes *state variables* for management (these are modified during the simulation):

Element	Description
yearsSinceThinning	State variable to count the years since the last thinning ocurred
finalPreviousStage	Integer state variable to store the stage of final cuts ('0' before starting final cuts)
finalYearsToCut	State variable to count the years to be passed before new final cut is applied.

**Remenber**: Besides using the in-built management function, you could program your own management function and specify its own set of parameters.
